Selecting Indicators for Acid-Base Titrations
Titrations – WA & SB/WB & SA

Introduction
Acids and bases vary in strengths and are normally classified as strong or weak. In any acid-base titration the neutralization, or equivalence point, occurs when the moles of acid in a solution are equal to the moles of base. However, the pH of the solution at this point can vary widely and depends on the strengths of both the acid and the base. How is an indicator selected that fits a particular acid-base titration?

Concepts
- Weak acid
- Equivalence point
- pH indicator
- Weak base
- Acid-base titration
- Conjugate acid-base pairs

Background
In acid-base titrations, the plot of pH versus volume of titrant results in an S-shaped curve (see Figure 1).

![Figure 1](image_url)

**Figure 1**
The steepness of the curve and the pH value at the equivalence point depend on the strength of both the acid and the base. If both the acid and base are strong, the curve is very steep and the equivalence point pH value is 7.

If a weak acid is titrated by a strong base, the titration curve is less steep and the equivalence point pH value is >7. At the equivalence point,

\[
\text{Moles of acid (HA)} = \text{moles of base (OH}^-) \text{ added} \\
\text{Or}
\]

\[
M_{HA} \times V_{HA} = M_{OH^-} \times V_{OH^-}
\]

The overall neutralization reaction is,

\[
\text{HA(aq)} + \text{OH}^-(\text{aq}) \rightarrow \text{A}^-\text{(aq)} + \text{H}_2\text{O(1)}
\]

Equation 1

At this point, the initial moles of the weak acid (HA) have been completely converted to its conjugate base (A^-). This conjugate base is a weak base and equilibrates with water to form a basic solution.

\[
\text{A}^-\text{(aq)} + \text{H}_2\text{O(1)} \rightarrow \text{HA(aq)} + \text{OH}^-(\text{aq})
\]

Equation 2

\[
K_b = \frac{K_w}{K_a}
\]

Where \( K_w = 1 \times 10^{-14} \) and \( K_a \) is the dissociation constant of the weak acid (HA).

The pH at the equivalence point is found by first calculating the pOH, of \(-\log[\text{OH}^-]\), of this solution of the weak base A^- and water.

The initial concentration of A-, before its reaction with water, is equal to the initial moles of weak acid, HA, present in the solution, divided by the volume of solution at the equivalence point.

When the weak base A- reacts with water, at equilibrium,

\[
[\text{HA}] = [\text{OH}^-] = x
\]

And \( [\text{A}^-] = \frac{\text{Initial moles of HA}}{\text{Volume of solution at the equivalence point}} - x \)

If \( [\text{A}^-] >> [\text{HA}] \), substituting these values into Equation 3 yields

\[
[\text{OH}^-] = x = K_b \times [\text{A}^-]
\]

Initial moles HA

Volume of solution at equivalence point

Since \( \text{pOH} = -\log[\text{OH}^-] \) and \( \text{pH} + \text{pOH} = 14.00 \)
Once this pH value is determined, an appropriate indicator can be selected for the titration. Indicators are mostly complex organic molecules that are themselves weak acids. If the indicator is represented by HIn, then in solution,

$$\text{HIn(aq)} + \text{H}_2\text{O(1)} \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{In}^{-}(aq) \quad \text{Reaction 3}$$

$$\text{With } \text{Ka} = \frac{[\text{H}_3\text{O}^+][\text{In}^{-}]}{[\text{HIn}]} \quad \text{Equation 4}$$

The HIn form has one color in solution and the In\(^-\) form has another. If Equation 3 is rearranged, then

$$\frac{\text{Ka}}{[\text{H}_3\text{O}^+]} = \frac{[\text{In}^{-}]}{[\text{HIn}]} \quad \text{Equation 5}$$

As base is added in the titration, H\(_3\)O\(^+\) ions are removed and the equilibrium shifts right, forming more In\(^-\) ions. A color change starts to occur when [In\(^-\)] is about one-tenth [HIn].

At this point,

$$\frac{[\text{In}^{-}]}{[\text{HIn}]} = \frac{\text{Ka}}{[\text{H}_3\text{O}^+]} = \frac{1}{10}$$

In terms of pH

$$\text{pKa} - \text{pH} = 1 \quad \text{or} \quad \text{pH} = \text{pKa} - 1 \quad \text{Equation 6}$$

For a specific titration of an acid by a base, an indicator is selected that has a pKa one unit above the pH value of the equivalence point. The color transition of the indicator is complete when,

$$\frac{[\text{In}^{-}]}{[\text{HIn}]} = \frac{10}{1}$$

Thus the transition range for most indicators is two pH units, or pKa ± 1.

When a weak base is titrated with a strong acid, all the weak base (B) is converted to its conjugate acid (BH\(^+\)) at the equivalence point.

$$\text{B(aq)} + \text{H}_3\text{O}^+(aq) \rightarrow \text{BH}^+(aq) + \text{H}_2\text{O(1)} \quad \text{Reaction 4}$$

The BH\(^+\) produced equilibrates with water to form an acidic solution.

$$\text{BH}^+(aq) + \text{H}_2\text{O(1)} \overset{\text{Kw}}{\rightleftharpoons} \text{B(aq)} + \text{H}_3\text{O}^+(aq)$$

$$\text{With } \text{Ka} = \frac{[\text{H}_3\text{O}^+][\text{B}]}{[\text{BH}^+]} \quad \text{Equation 7}$$
At equilibrium of the weak acid BH$^+$ and water,

$$[B] = x = [H3O^+]$$

Initial moles of B

And $$[BH^+] = \frac{\text{Initial moles of B}}{\text{Volume of solution at equivalence point}}$$

Experimental Overview

The appropriate indicators are selected for two titrations—a weak acid titrated with a strong base solution and a weak base solution titrated with a strong acid solution. The indicators are added to the solutions and the solutions are titrated. Titration curves of pH versus volume of titrant are generated and used to verify the appropriateness of the selected indicators.

Pre-Lab Questions and Calculations

1) In Part 1 of this lab, 25.0 mL of a 0.100 M solution of the weak acid acetic acid, CH$_3$COOH, is titrated with a 0.100 M solution of the strong base sodium hydroxide, NaOH. $K_a$ of acetic acid is $1.8 \times 10^{-5}$.

   a) Calculate the pH of the equivalence point. Enter this value into the Part 1 Data Table.

   b) Five indicators, along with their $pK_a$ values and their color ranges, are listed in the table below.

Based on the pH calculated in 1a, select the appropriate indicator for the weak acid—strong base titration. Enter the selection in the Part 1 Data Table.

2) In Part 2, 2.50 mL of a 0.10 M solution of the weak base ammonia, NH$_3$, is titrated with a 0.10 M solution of the strong acid hydrochloric acid, HCl. $K_b$ of ammonia is $1.8 \times 10^{-5}$.

   a) Calculate the pH of the equivalence point. Enter this value in the Part 2 Data Table.

   b) Select the appropriate indicator for the weak base—strong acid titration. Enter the selection in the Part 2 Data Table.

3) 25 mL of a 0.10 M solution of the weak acid hydrofluoric acid, HF, is titrated with a 0.10 M solution of the weak base ammonia, NH$_3$. Will the pH at the equivalence point be less than 7, equal to 7, or greater than 7? Explain. $K_a$ for HF is $7.2 \times 10^{-4}$ and $K_b$ for NH$_3$ is $1.8 \times 10^{-5}$.

Procedure:

Part I. Titration of a Weak Acid with a Strong Base

1. Place about 75mL of 0.10 M acetic acid solution in a clean 250- mL beaker.
2. Using a clean 25-mL volumetric pipet, quantitatively transfer 25.0 mL of 0.10 acetic acid solution to a clean 150-mL beaker.
3. Obtain about 100 mL of the 0.10 M NaOH solution in a clean, 250-mL beaker.
4. Clean a 50-mL buret thoroughly with tap water, then rinse it with several small portions of the standard NaOH solution, being sure to run some solution through the tip.
5. Attach the buret clamp to the ring stand. Place the buret in the buret clamp.
6. Fill the buret above the 0-mL mark, then lower the meniscus back to the 0-mL mark.
7. Set up a pH meter and electrode on the ring stand. Calibrate the pH meter using a buffer solution of pH 7.00. Rinse the electrode well with distilled water.

8. Set the beaker containing the acetic solution on a magnetic stirrer so that the buret tip is just below the lip of the beaker. Clamp the pH electrode so it is submerged in the acid solution (Figure 3). Be sure the stir bar does not hit the electrode. Set the stir bar gently spinning.

9. When the pH reading has stabilized, record the initial pH of the solution in Part 1 Data Table.

10. Add 3 drops of the indicator selected for this titration in the Pre-Lab Calculations section. Record the solution color in the Part 1 Data Table.

11. Add about 1 mL of sodium hydroxide solution to the beaker. Record the exact buret reading in Part 1 Data Table.

12. Record the pH and the color of the solution next to the buret reading in the Part 1 Data Table.

13. Add another 1-mL increment of sodium hydroxide solution. Record the buret reading, the pH, and the solution color in Part 1 Data Table.

14. Continue adding sodium hydroxide in 1-mL portions. Record the buret reading, the pH, and the solution color after each addition.

15. When the pH begins to increase by more than 0.3 pH units after an addition, decrease the portions of sodium hydroxide added to about 0.2 mL.

16. Continue adding sodium hydroxide in about 0.2 mL increments. Record the buret reading, the pH, and the solution color after each addition.

17. When the pH change is again about 0.3 pH units, resume adding the sodium hydroxide in 1-mL increments. Continue to record the buret reading, the pH, and the solution color after each addition.

18. Stop the titration when the pH of the solution is greater than 12. Record the final volume of solution in the buret, final pH, and solution color.

19. Repeat the titration. If the indicator selected did not change color at the equivalence point in the first titration, review the Pre-Lab Calculations and select another indicator.

**Part II. Titration of a Weak Base with a Strong Acid**

1. Place about 75 mL of 0.10 M ammonia (NH₃) solution in a clean 250-mL beaker.

2. Using a clean 25-mL volumetric pipet, quantitatively transfer 25.0 mL of 0.10 M NH₃ solution to a clean 150-mL beaker.

3. Obtain about 100 mL of 0.10 M hydrochloric acid (HCl) solution in a clean, 250-mL beaker.

4. Rinse the 50-mL buret with three small portions of deionized water, then rinse it with several small portions of 0.10 M HCl solution. Place the buret back in the buret clamp.

5. Fill the buret with 0.10 M HCl solution above the 0-mL mark, then lower the meniscus back to zero.

6. Set the beaker containing the 0.10 M NH₃ solution on a magnetic stirrer. Clamp the pH electrode so it is submerged in the basic solution. Be sure the stir bar does not hit the electrode. Set the stir bar gently spinning.

7. When the pH reading has stabilized, record the initial pH of the solution in Part 2 Data Table.

8. Add three drops of the indicator selected for this titration in the Pre-Lab Calculations section. Record the solution color in the Part 2 Data Table.

9. Add about 1 mL of 0.1 M HCl solution to the beaker. Record the exact buret reading in Part 2 Data Table.
10. Record the pH of the solution and the solution color next to the buret reading in the Part 2 Data Table.
11. Add another 1-mL increment of hydrochloric acid solution. Record the buret reading, the pH, and the solution color in Part 2 Data Table.
12. Continue adding hydrochloric acid in 1-mL portions. Record the buret reading, the pH, and the solution color after each addition.
13. When the pH begins to decrease by more than 0.3 pH units after an addition, decrease the portions of 0.10 M HCl added to about 0.2 mL.
14. Continue adding 0.10 M HCl in about 0.2 mL increments. Record the buret reading, the pH, and the solution color after each addition.
15. When the pH change is again about 0.3 pH units, resume adding the 0.10 M HCl in 1-mL increments. Continue to record the buret reading, the pH, and the solution color after each addition.
16. Stop the titration when the pH of the solution is less than 2. Record the final volume of solution in the buret, the final pH, and the final solution color.
17. Repeat the titration. If the indicator selected did not change color at the equivalence point in the first titration, review the Pre-Lab Calculations and select another indicator.

**Data Table** (They need to be much larger to record more data)

**Graphs and Calculations**

Graph the pH versus the mL of titrant for each of the titrations. Make sure the graph is large enough to reflect the care taken with measuring the pH and volume. Draw the best fitting smooth curve for the data. Label the equivalence point. Indicate the indicator color for each data point. Were the indicators selected appropriate for the two titrations? If not, why?
