IONIC EQUILIBRIA OF ACIDS and BASES (Ch. 14 (sec.1-5)
THEORY
SOLVENT RESTRICTIONS
ACID
BASE

| Arrhenis | Aqueous only | $\mathrm{H}_{3} \mathrm{O}^{+}\left(\mathrm{H}^{+}\right)$ | $\mathrm{OH}^{-}$ |
| :--- | :--- | :--- | :--- |
| Bronsted-Lowry | Protonic solvents | Proton donor | Proton acceptor |
| Lewis | None | e-pair acceptor | e-pair donor |

$B / L$ Theory is followed mostly - where conjugate base (CB) - accepts a $\mathrm{p}^{+}$and conjugate acid donates a $\mathrm{p}^{+}$

$\mathrm{Kw}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]$
So each concentration $(M)$ of hydronium and hydroxide $=1.0 \times 10^{-7} \mathrm{M}$
Remember $\left[\mathrm{H}^{+}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$
Also strong electrolytes ionize totally in solution and weak electrolytes, only partially.
Ex: HCl (monoprotic acid) will ionize totally to:

****because the moles of water consumed in the formation of hydronium are negligible compared to the \# of moles present, $M$ is constant, so no need for it in the $K_{A}$.
$\mathrm{K}_{\mathrm{A}}$ is the acid dissociation constant. It equals the concentration of the products/ concentration of reactants.

The higher the $\mathrm{K}_{\mathrm{A}}$, then the stronger the acid and the more it dissociates. Same thinking for bases. (K $\mathrm{K}_{\mathrm{B}}$ )

- There are, however, many strong acids that don't have an equilibrium constant. Why? Concentrations can be found from the molar concentration of the solution.

So, most of the time when equilibrium constants are found for acids or bases, it is because they are weak!

Weak acids will only slightly ionize in water:
(Ch.14.2-p.661)
Ex: (in general) $\mathrm{HA}+\mathrm{OH}^{-} \rightarrow \mathrm{A}^{-}+\mathrm{H}_{2} \mathrm{O}$
$\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}+\mathrm{OH}^{-}--\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}+\mathrm{H}_{2} \mathrm{O}$

REVIEW OF pH (Ch14 p.666)
Neutral
$\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]$

$$
\begin{aligned}
& \mathrm{pH}=-\log \left[\mathrm{H}^{+}\right] \\
& \mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]
\end{aligned}
$$

Basic
$\left[\mathrm{H}^{+}\right]<\left[\mathrm{OH}^{-}\right]$

$$
\mathrm{K}_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]+\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}
$$

(refer to self-ionization equation)

## Calculating the pH of Strong Acid Solutions

In attacking acid-base equilibrium problems, writing the major species in the solution is VITAL! Example 14-7 p. 670

1. Calculate the pH of $.10 \mathrm{M} \mathrm{HNO}_{3}$.

It is a strong acid and the major species are: $\mathrm{H}^{+}, \mathrm{NO}_{3}{ }^{-}, \& \mathrm{H}_{2} \mathrm{O}$
The M of the acid is pretty much 0 , since the acid completely dissociates. The hydroxide ion concentration will be very small too because the hydronium ions from the acid drives equilibrium to the left. So the sources of hydronium ion are from $\mathrm{HNO}_{3}(.10 \mathrm{M})$ and from $\mathrm{H}_{2} \mathrm{O}$.

The $\mathrm{H}^{+}$ions contributed by the self-ionization of water is so small, it can be ignored compared to the ions coming from the $.10 \mathrm{M} \mathrm{HNO}_{3}$.

So, $\left[\mathrm{H}^{+}\right]=.10 \mathrm{M}$ and $\mathrm{pH}=-\log [.10]=1.00$ (very acidic)
2. Calculate the pH of $1.0 \times 10^{-10} \mathrm{M} \mathrm{HCl}$.

The amount of HCl in solution is very small, so the only major species is $\mathrm{H}_{2} \mathrm{O} . \mathrm{pH}=7.00$

## Calculating the pH of Weak Acids (starts with Ch 14.5)

Calculate the $\left[\mathrm{H}^{+}\right]$and \% ionization of .0092 M H CIO is given:
(like 14.10- p.678-good supplemental article on p.679)
Write the species involved:
$\mathrm{HClO} \underset{\leftarrow---}{\rightarrow} \mathrm{H}^{+}+\mathrm{ClO}^{-}$
$\mathrm{K}_{\mathrm{A}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{ClO}^{-}\right]}{[\mathrm{H} \mathrm{CIO}]}=$
$3.5 \times 10^{-8} \quad$ (found on a reference table)
The amount of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$in solution that is from $\mathrm{H}_{2} \mathrm{O}$ is too small and can be ignored.

|  | $[\mathrm{H} \mathrm{ClO}]$ | $\left[\mathrm{H}^{+}\right]$ | $[\mathrm{ClO}]$ |
| :--- | :--- | :--- | :--- |
| Initial | .0092 | 0 | 0 |
| Equilibrium | $.0092-x$ | X | X |

$\mathrm{X}=\left[\mathrm{H}^{+}\right]=\left[\mathrm{ClO}^{-}\right]$
[ H CIO] $=.0092-x$
$\mathrm{K}_{\mathrm{A}}=3.5 \times 10^{-8}=\underline{\underline{x}}^{\underline{2}}$
.0092-x
${ }^{*_{* *}}$ if the concentration of ionizing substance and $\mathrm{K}_{\mathrm{A}}$ differ by $5 \%$ or more, than x can be neglected in the denominator. (otherwise, you have to plug it in to your favorite of all time...the quadratic formula!!!)

So, $=3.5 \times 10^{-8}=\underline{x^{2}}$
.0092
$x=1.8 \times 10^{-5} \mathrm{M}=\left[\mathrm{H}^{+}\right]=\left[\mathrm{ClO}^{-}\right]$
$\frac{1.8 \times 10^{-5} \mathrm{M}}{0092 \mathrm{M}}$
$X 100=\%$
part/total $=\%$ ionized in a WA
